### A B S T R A C T

Over the last decade, most credit-industries registered a decline in lending volumes, while factoring industries instead registered a substantial growth in terms of turnover. Surprisingly, only a handful of papers so far investigate factoring companies. Do factoring firms display the same stability levels of banks? Is the competition similar in factoring and banking industries? Is the relationship between competition and stability the same in these industries? Focusing on Italy (one of the largest factoring and banking markets in Europe) and using a unique dataset, we show three main results: factoring companies are (on average) more stable than banks; 2) the stability of factoring companies increase when competition declines (competition-fragility view); 3) the competition-fragility view is weaker in the factoring industry than in the banking industry. Our findings indicate that competition in the Italian credit industry was greater in factoring than in banking.

## 1. Introduction

In the last decade, most credit-industries registered a decline in lending volumes, while factoring industries instead registered a substantial increase in terms of volume. Since the Global Financial Crisis of 2008, many firms, particularly SMEs, experienced greater difficulty in obtaining traditional bank funding. Conversely, the financial crisis increased companies' demand for trade-credits, and this explained the increase for factoring services. In particular, the total factoring volume in EU increased by 62% (from €990 to €1606 in billions) over the period 2010–2017. Factoring provides a mix of financial services<sup>4</sup> including credit protection, receivable management, and collections. It has now become a primary source of funding for most firms in Europe (the factoring and commercial finance was 10.4% of European GDP in 2016). Like banks, factoring companies are supervised in most European countries and it is critical for supervised authorities to understand if a greater competition in the industry would lead factoring companies to increase their risk-taking (e.g. financing riskier borrowers to increase their

market power) or decrease their risk taking (e.g. becoming more selective in screening borrowers to minimize credit losses). The good functioning of the factoring industry is important to provide greater financing flows to companies.

The competition-stability nexus has gathered a lot of attention in the banking literature (Goddard & Wilson, 2009; Wilson, Casu, Girardone, & Molyneux, 2010). Surprisingly however, past papers have essentially focused on the banking industry, omitting to consider other sectors within the credit industries. This is mostly due to the lack of data in non-banking financial institutions. This paper covers this gap and provides new findings on the relationship between competition and stability in the factoring industry. The main contribution of our study to the existing literature dealing with the link between competition and stability is that, as far as we are aware, this denotes the first attempt at investigating this issue in a non-banking credit sector, such as the factoring industry.

Specifically, we test our hypotheses by jointly analysing banking and factoring firms and controlling for bank characteristics and macroeconomic determinants. Firm stability is estimated using two variables: the Z-score and the Capital at Risk (CAR). Competition is estimated using the Lerner Index which is employed extensively in the existing banking literature (Carbò, Humphrey, Maudos, & Molyneux, 2009; Cipollini & Fiordelisi, 2012; Liu & Wilson, 2013; Liu, Molyneux, & Wilson, 2013; Fiordelisi & Mare, 2014; Degl'Innocenti, Fiordelisi, Girardone, & Radić, 2019, 2018; Clark, Davide, & Radić, 2018; Fiordelisi, Mare, & Molyneux, 2018). We use a panel-data vector auto-regression to examine the link between competition and bank risk measures.

Furthermore, we make use of a unique dataset of Italian factoring companies ("Osservatorio sugli Intermediari Finanziari Non Bancari" (OSSFIN) database). Our focus is on Italy for various reasons. First, credit institutions are major players in the Italian financial systems and, of course, banks are the most important credit institutions. However, factoring companies have grown consistently during the last decade and the Italian factoring industry is one of the major factoring markets in Europe with a total turnover of 209 Euro billions, i.e. 13.9% of the whole European market and 12.5% of the Italian GDP.<sup>5</sup> Second, factoring companies are supervised as specialized financial intermediaries and the link between competition and stability (both are aims of the supervisory authority) is crucial both in banking (where there is extensive evidence) and the factoring industry.

We find four main results. First, we show a positive link between firm market-power and stability in the credit industry (both factoring and banking) supporting the competition fragility-view. Second, factoring companies are (on average) more stable than banks in the Italian credit industry. Third, we show that the competition-fragility view is weaker in the factoring industry than in banking. Fourth, the impulse responses of risk variables to variation in competition degree, and vice versa, mainly show significant patterns for the factoring industry. Particularly, we find a significant and negative response of the Z-score and the CAR in the short run to possible shocks in the Lerner Index, but such an effect tends towards zero in the medium term. Finally, we find evidence that the Lerner Index decreases as the effect of a shock in the Z-score, while increases because of a shock in the CAR in the factoring industry.

Our paper provides new important insights to policy makers, practitioners, and academics that there are differences between factoring firms and banks in terms of stability (greater in factoring), competition (greater in factoring), and in their relationship (where the competition-fragility view is weaker in factoring). Overall the factoring industry appears to be more stable than commercial banks and less vulnerable to financial crises because of the peculiarity of its business model. However, policy makers should be aware of the fact that the level of stability of the sector could decrease as the effect of the consolidation process and a consequent increase of the factoring firms' market share. Furthermore, the creation of a niche of specialization in terms of industrial and geographic markets could further enhance the monopoly market power of certain financial intermediaries in the factoring industry in this way harming both the competition and the stability of the financial industry. In spite of the idiosyncrasies of the factoring business, commercial banks could still look at the practices adopted in the factoring industry to advance risk management (and potentially decrease non-performing loans).

The paper is organised as follows. Section 2 provides an overview of the factoring industry in Italy. Section 3 discusses the literature review and the hypotheses; Section 4 presents the methodology (Section 4.1) and the estimation procedure for the competition measures (Section 4.2) and stability (Section 4.3). Section 5 presents the data. Section 6 reports the summary statistics and preliminary investigation, while Section 7 describes the empirical findings. Finally, Section 8 concludes.

## 2. An overview of the factoring industry in Italy<sup>6</sup>

Since the 2008 financial crisis, the Italian factoring industry has seen a strong increase of almost 72.3% in terms of turnover. Furthermore, the relevance of the total turnover for factoring in Italy is almost 13% of the GDP and it has seen an increase of almost of 23% over the period 2011–2016. Nowadays, factoring represents one of the major sources of firms to finance their working capital especially for firms operating in the manufacturing, service, and retail sectors in Europe (Table 1).

Factoring services can be offered by bank-related, independent, captive firms or banks. Commercial banks tend to create an ad-hoc firm within the group that deals with factoring services/products (e.g. UBI factor, Unicredit Factoring). Financial intermediaries that belong to a banking group cover almost 50% of the entire market in terms of turnover. Captive firms refer instead to firms that have been created by industrial groups to offer factoring products/services (e.g. GE capital), while

independent firms do not do belong to any group. Captive and independent firms deal with more than 10% of the total factoring turnover in Italy, while the remaining market share belongs to banks.

In Italy, factoring firms are financial intermediaries subject to equivalent regulatory requirements of the banking sector (for example in terms of capital reserves and loan loss provisioning) based on the principle of proportionality. Instead, due to the characteristics of the business, factoring firms do not usually hold off-balance sheet activities. Furthermore, differently from banks, factoring firms cannot collect deposits.

### 3. Literature review and research hypotheses development

The banking literature has already thoroughly examined the link between competition and stability (Goddard & Wilson, 2009; Wilson et al., 2010). Higher competition is often related to more innovation (Cornaggia, Mao, Tian, & Wolfe, 2015), greater efficiency (Casu & Girardone, 2009; Schaeck & Cihak, 2014), higher quality products and better prices for customers (Anginer et al., 2014), or it entails holding more capital (Beck, Demirgüç-Kunt, & Levine, 2006; Schaeck, Cihak, & Wolfe, 2009). The economic conditions at the regional level play a pivotal role in affecting the stability of European banks (Liu et al., 2013). Moreover, from a social welfare perspective, greater competition contributes to decrease the deadweight loss generated by market power via lower spreads (i.e., Harberger's triangle - lower output and higher price) (Chortareas, Garza-García, & Girardone, 2012). However, competition can also harm the "charter value" of banks, in this way increasing the instability of the financial system (Allen & Gale, 2004). Maximum welfare may engender negative externalities if it lowers bank stability. Indeed, regulation is justified by the presence of important barriers to entry that prevent proper contestability in banking triggering a more pervasive role for supervisors. Regulation is a particularly intricate determinant to assess as it can for instance a) soften competition by rising barriers to entry, b) restrict banking activities, and c) alter the competitive position of banks via prudential rules (Degryse & Ongena, 2007).

The theoretical concerns hinges on the link between competition and stability (Allen & Gale, 2004; Boyd & De Nicolò, 2005; Keeley, 1990). Several studies try to assess the extent of this trade-off. For example, Anginer et al. (2014) show that competition can increase stability at the systemic level. Other scholars, (e.g. Boyd, De Nicolò, and Al Jalal (2006) and De Nicolò and Loukoianova (2007)) point out that financial instability can increase in systems with low competition. In contrast, Beck et al. (2006) argue that more concentrated banking markets exhibit a lower likelihood of incurring systemic crises and might be more resilient than competitive markets. This is reasonable as, for instance, a well-organised cartel could be more effective in increasing stability than a large number of small competing banks or few larger institutions, which can be easier to monitor (Allen & Gale, 2000). Yet if so, this could involve a welfare cost. Cross-country empirical findings on the causality between competition, concentration and risk is mixed. Focusing on 45 countries over the period 1980–2005, Schaeck et al. (2009) show that more competitive and less concentrated banking markets are less likely to incur a systemic crisis. Fu, Lin, and Molyneux (2014), focusing on the Asia Pacific countries, postulate that concentration increases bank instability and that lower market power induces higher financial fragility. Focusing on 23 developed countries, Berger, Klapper, and Turk-Aris (2009) show that bank market power can enhance riskier portfolios. However, they also find that the decrease of stability can be counterbalanced by a greater franchise value. Some recent papers employ multifarious factors able to explain the dynamics of the relationship such as regulation, institutional elements, and the economic environment. So far, a few papers have investigated the role of systemic risk and related the cost of government intervention to market power. Fiordelisi and Mare (2014) analyse European cooperative banks and find that the financial crisis of 2007 does not affect the negative link between market power and bank stability. Soedarmono and Tarazi (2015) advocate that the financial crisis has modified market competitiveness and triggered banking reforms. Therefore, we posit that market power can in part shield financial institutions from economic downturns through for instance a margin effect (Martinez-Miera & Repullo, 2010), higher profits, and capital buffers (Allen & Gale, 2004).

Various financial intermediaries are exposed to different sources and degrees of risk. Amongst them, the financial intermediaries specialized in the factoring sector appear to experience less loss rates compared to banks dealing with traditional banking credit in Europe.<sup>7</sup> In Italy, the percentage of non-performing loans on bank loans was above 10% in 2016 while it barely reached the 4–5% in the case of the factoring industry.<sup>8</sup> This difference of performance between these financial intermediaries can be traced to the peculiarities of the factoring sector since the funding is made against the trade receivables of the user business. Furthermore, the credit risk is distributed amongst the business' debtors. This makes this form of funding

<sup>7</sup> Source: EUF (2015).

<sup>8</sup> Source: Assifact (2018).

less risky and accessible for small and less established firms. In addition, within Europe, the factoring sector is dominated by a variety of players (mainly represented by banks and bank-related financial intermediaries), which can be specialized on various industrial and geographical markets. This can affect the way these financial intermediaries compete with each other.

<sup>11</sup> We therefore formulate the following questions: is the competition and stability of factoring companies similar to banks? Is the relationship between competition and stability the same in the banking and factoring industries? And does a greater level of competition increase risk-taking in the factoring industry (the competition-fragility view<sup>9</sup>) or does it reduce risk-taking (the competition-stability view<sup>10</sup>)? We investigate whether factoring firms and commercial banks are exposed to the same competition-stability relationship. This could be relevant to understand the mechanisms underlying stability in a heterogeneous financial ecosystem characterized by various financial players more or less specialized in a particular product or service. The next section explains the data and the empirical strategy that we employ to address our research questions.

#### 4. Methodology and description of the variables

##### 4.1. The link between risk and competition

To assess the risk-competition link, we employ a panel-data vector auto-regression approach (PVAR)<sup>11</sup> that accounts for endogeneity concerns because of the reverse causality between risk and competition and allows for an examination of the impulse responses of risk measures to variations in the degree of competition (and vice versa). In particular, our baseline model is as follows<sup>12</sup>:

$$Y_{it} = Y_{it-1}A_1 + X_{it}B + u_i + e_{it} \quad (1)$$

where  $Y_{(t)}$  includes risk and competition measures. Both risk and competition measures are considered as endogenous variables.  $X_{it}$  consists of a vector of exogenous covariates, and  $B$  is the matrix of the parameters to be estimated. Finally,  $u_i$  is the vectors of dependent variable-specific panel fixed-effects. Finally,  $e_{it}$  indicates idiosyncratic errors.

To reduce endogeneity issues due to omitted variables, we have time-demeaned the original variables. In addition, we have removed fixed individual effects. Next, we employ the GMM estimator of the model transformed by the forward orthogonal deviation that appear to perform better than the first difference (Hayakawa, 2009). For our analysis, we use traditional instruments, as our period is relatively short. As pointed out by Hayakawa (2016, 2019), conventional estimators using instruments in levels have comparable sample properties to the new instruments in a univariate AR(p) when T is small.

Additionally, we run panel unit-root tests and we found no unit roots in the endogenous variables. Concerning this, as stressed by Abrigo and Love (2016), the GMM estimator can suffer from weak instrument issues if the endogenous variables exhibit a unit root. Next, we employ the procedure proposed by Andrews and Lu (2001) for GMM models. This allows us to choose the number of lags to include in the model based on Hansen's (1982) J statistic of over-identifying restrictions. The test indicates that one lag is optimal. As suggested by Hayakawa (2016), we employ generalized IRFs that do not depend on the ordering of variables as orthogonalised IRFs do. Then, we generate bootstrapped confidence intervals to get the impulse response functions by running 1000 Monte Carlo simulations.

Finally, we present the forecast-error variance decomposition (FEVD). This allows us to assess the percentage of change in risk (competition) explained by the 'shock' to competition (risk) over time. FEVD is calculated following the Cholesky decomposition of the residual covariance matrix obtained with the panel VAR approach. As suggested by Abrigo and Love (2016), we do not consider the exogenous variables when computing FEVD.

The set of covariates,  $X_{it}$ , includes market share and performance. The latter one is calculated by using the return on assets, ROA. On the one hand, banks with a high market share or performance can wield a greater market power because of cost advantages and the capability to set higher prices (e.g. Carbo et al., 2009; Clark et al., 2018; Fernandez De Guevera et al., 2005). On the other hand, financial institutions with high market share and size in the market could also undertake risk-taking behaviour under the perception that big banks will be bailed-out if they find themselves in a distressed situation (e.g. Dam & Koetter, 2012; Hakenes & Schnabel, 2010).

##### 4.2. Measuring industry competition

In order to measure market conditions in the banking and factoring industries, we employ both non-structural and structural indicators of competition. Specifically, we use a structural indicator of competition, i.e. the market share of each firm computed based on total assets. Differently from the Herfindahl-Hirschman Index (HHI), the market share allows us to investigate the competitive dynamics of each firm.

<sup>9</sup> Allen and Gale (2004); Forssbäck and Shehzad (2015).

<sup>10</sup> Boyd and De Nicolò (2005); De Nicolò and Lucchetta (2009).

<sup>11</sup> For our analysis we use the Stata program developed by Abrigo and Love (2016).

<sup>12</sup> For recent applications of the model proposed by Love and Zichino (2006) and Abrigo and Love (2016) see e.g. Degl'Innocenti et al. (2018, 2019), Delis, Hasan, and Kazakis (2014), Head, Lloyd-Ellis, and Sun (2014).

We also use a non-structural indicator capturing competition at the bank individual level. Particularly, we use the Lerner index of monopoly power ( $LER$ ), that has been largely adopted in past studies analysing competition in banking (recently, Turk-Ariss, 2010; Fiordelisi & Mare, 2014; Forssbäck and Shehzad, 2014; Degl'innocenti, Mishra, & Wolfe, 2018, 2019; Clark et al., 2018).

The Lerner index indicates a firm's capability to fix prices above its marginal production cost ( $LER = (P_{it} - MC_{it})/P_{it}$ ), where  $P$  is the average selling price and  $MC$  is the marginal cost of production. For both factoring companies and banks, we define one single output,  $Y_{it}$  capturing the whole activity of the firm that is total earning assets. The output price,  $P_{it}$ , is approximated by the ratio between total interest revenues and turnover in the case of factoring companies, and by the ratio between total revenue and total assets in the case of banks.

The estimation of the marginal cost needs the definition of the cost function for firms competing in the industry. Two very important issues have been addressed here: the definition of inputs and outputs in the banking and factoring industries; and the form of the cost function in the industry. Regarding the first issue, we define a single output ( $Y_{it}$ ) for both factoring companies and banks (the total earning assets for banks) and three inputs for both factoring companies and banks. For both types of financial companies, these are measured in the same way: human capital ( $X_{1it}$ ) measured by the total staff expenses; physical capital ( $X_{2it}$ ) measured by the total value of tangible assets; and financial capital ( $X_{3it}$ ) proxied by the total liabilities. Consequently, we define the input prices as follows: human capital price ( $W_{1it}$ ) is obtained as the total personnel expenses and total assets; physical capital price ( $W_{2it}$ ) is calculated as the ratio of other operating expenses and other administrative expenses to total fixed assets; and financial capital price ( $W_{3it}$ ) is calculated as the total interest expenses over total liabilities. Regarding the second issue, we define a translog cost function (consistently with past papers, as Liu & Wilson, 2013; Fiordelisi & Mare, 2014; Forssbäck & Shehzad, 2015; Clark et al., 2018; Degl'Innocenti et al., 2019),<sup>13</sup> for each industry as follows:

$$\ln(TC_{it}) = \beta_0 + \beta_1 \ln Y_{it} + \sum_{h=1}^3 \beta_h \ln W_{hit} + \frac{1}{2} \beta_{YY} (\ln Y_{it})^2 + \frac{1}{2} \sum_{h=1}^3 \sum_{m=1}^3 \beta_{hm} \ln W_{hit} \ln W_{mit} + \sum_{h=1}^3 \beta_{Yh} \ln Y_{it} \ln W_{hit} + \tau_1 T + u_{it} + v_{it} \quad (2)$$

for ( $h \neq m$ ) where  $TC$  denotes total cost (including personnel and administrative expenses, and interest expenses),  $W_{hit}$  are the input factors of the cost function defined for factoring companies and banks. Marginal costs can be calculated from equation (1) by considering the derivative relating to the single output ( $Y_{1it}$ ), which yields:

$$MC_{it} = \frac{TC_{it}}{Y_{it}} \left[ \beta_1 + \beta_{YY} \ln Y_{it} + \sum_{h=1}^3 \beta_{Yh} \ln W_{hit} \right] \quad (3)$$

Since banking and factoring industries have different features (e.g. banks have a distribution system based on a large number of branches and offer a wide range of financial services; factoring companies have typically few branches and focus on trade credit), we cannot safely control for all differences estimating a common cost function. As such, we estimate a specific cost function for each of the two industries.

#### 4.3. Measuring industry stability

We use two main risk measures for our analysis. Specifically, we calculate the banks' Capital-At-Risk (CAR) that indicates how much capital a firm or bank would need to offset the risks that it is facing as a running concern. For the scope of the paper, we calculate the Earning at Risk (EAR), which is the worst change in earnings that a bank or firm is facing over a fixed-time horizon given a fixed confidence level. EAR is a common risk measure in the banking literature (Andrén, Jankensgard, & Oxelheim, 2005; Stein, Usher, La Gattuta, & Youngen, 2001).

EAR is computed as follows:

$$EAR = \eta + z_{(1-\alpha)/2} \sigma \quad (4)$$

where  $\eta$  measures the firm or bank's profit before tax (PBT);  $\sigma$  indicates the standard deviation of PBT; and  $z_{(1-\alpha)/2}$  is the probability related to the  $\alpha$  confidence level. In this case, we assume that earnings follow a normal distribution. Specifically, CAR then indicates the amount of equity equivalent to the current value of perpetuity of EAR that a firm needs to keep under the expectation that earnings will decrease permanently or over a longer term. The formula presents the following form:

$$CAR = EAR/ROE \quad (5)$$

<sup>13</sup> We run stochastic cost frontier model for panel data.

where ROE indicates the mean value of return on equity. A higher value of CAR suggests a higher risk for a firm or bank. Secondly, we introduce a bank stability measure that is the Z-score. This measure has been widely employed in the banking literature (e.g. Danisewicz, McGowan, Onali, & Schaeck, 2017; Laeven & Levine, 2009; Radic, Girardone, & Fiordelisi, 2012). This measure is constructed as the ratio of the return on assets (ROA) plus the capital at risk (CAR) divided by the standard deviation of ROA ( $\sigma_{ROA}$ ). Consistently with Hesse and Cihák (2007), we calculate a time varying indicator of bank stability. Specifically,  $\sigma_{ROA_t}$  is computed employing a cross-sectional approach and combining this with  $CAR_t$  and  $ROA_t$  at time  $t$  for each firm/bank. Higher values of Z-score indicate higher degree of solvency and bank soundness. We take the log of the Z-score.

## 5. Data

The lack of past studies dealing with non-banking credit companies is mainly due to the lack of data. For the Italian factoring industry data was obtained by collecting the financial reports of supervised factoring companies in Italy from the OSSFIN. There are no public source of information or data for factoring firms. On the contrary, there are various sources of data for banks. Specifically, we obtained data for 75 commercial banks over the period 2008–2015 from Fitch-IBCA BankScope (BSC). Overall, our sample includes both factoring and banking companies: we collected data for 33 factoring companies over the period 2008–2015 (707 firm-year observations). The number of observations is reported in Table 2.

We also summarize the definition and calculation procedure of our main variables in Table 3.

## 6. Summary statistics and preliminary investigation

In this section, we report the summary statistics of the variables included in the model (Table 4). We observe a high variability among the firms included in the dataset in terms of size, Z-score and CAR.

By looking at the industry competition, the Lerner Index (and the variables related to the inputs and outputs used to run the cost translog function) shows a similar mean level of competition in banking and factoring industries (i.e. 0.488 and 0.409, respectively). The magnitude of the Lerner index is quite modest suggesting that the competition is high in both industries. The lower level of market power in the factoring sector is driven by low prices. Specifically, the mean ratio of interest rates

**Table 2**

**Sample composition.** This table reports the number of firm-observations in our sample for each year in Italy between 2008 and 2015 by distinguishing between the factoring and banking industry.

| Type of Institutions | 2008 | 2009 | 2010 | 2011 | 2012 | 2013 | 2014 | 2015 | Total      |
|----------------------|------|------|------|------|------|------|------|------|------------|

over the turnover (total flow of traded credit) declined by 0.59% in 2012 to 0.36% in 2016 and, similarly, the mean ratio of interest rates over the mean loan (i.e. annualized flow of traded credit) declined by 3.28% in 2012 to 2.06% in 2016.

Next, we report a preliminary investigation by comparing our stability and competition measures in the factoring and banking industries. Specifically, Fig. 1 indicates the change of competition indicators in the factoring and banking industry. What emerges is that the competition level of the factoring market between 2008 and 2009 is higher than the one in the banking industry (Fig. 1c). Specifically, the HHI evolution between 2008 and 2015 show both a substantially lower concentration (Fig. 1a vs. 1c) in the factoring industry than in banking, and a lower market power (Fig. 1b and d). Interestingly, we observe that the concentration has slightly increased in the factoring industry between 2008 and 2015, but this is not associated with a greater market power of factoring firms. Conversely, we note the slight decline in the banking sector, which is related to a market power increase (between 2010 and 2014). Both for factoring and banking companies, we note a decline in market power in 2015 ( $t = 8$ ).

To have a first statistical test of differences between banks and factoring companies, we run a two-sample  $t$ -test with equal variance between the Lerner Index (Table 5). The results shows that the market power (Lerner Index) of factoring firms, on average equal to 0.403, is statistically and significantly lower than that of commercial banks, which on average is equal to 0.484. This is further evidence that competition in the Italian credit industry was greater in factoring than in banking.

## 7. Results

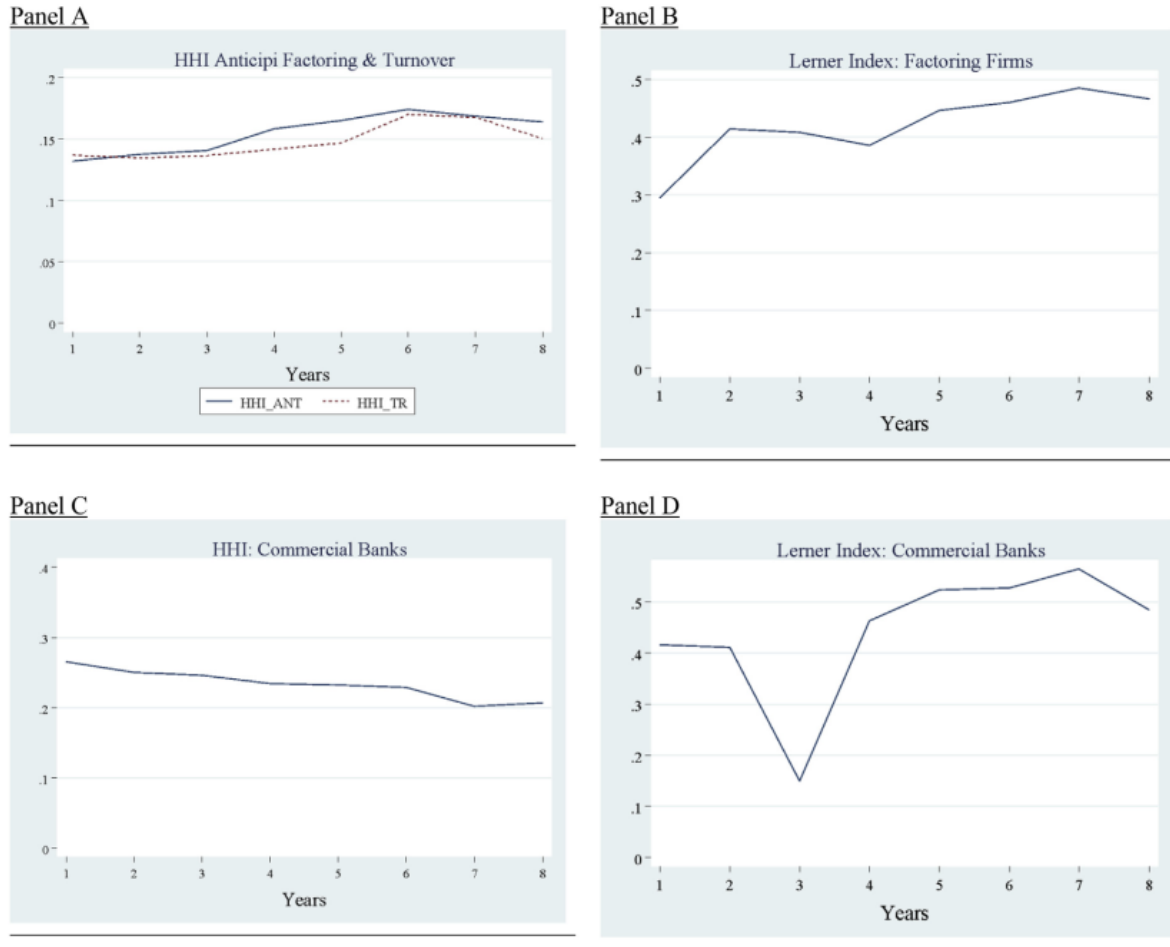

### 7.1. Main results

We employ a panel fixed effect model to assess the effect of competition on risk measures, Z-score, and CAR. To start, we estimate the joint impact of the Lerner Index and the type of credit institution (factoring vs banking) on firm stability (Z-score). Specifically, we have created a dummy (labelled Factoring), which is equal to 1 for factoring firms, and zero otherwise (banks). Therefore, we can distinguish between factoring firms and commercial banks and to better control for intra-industry competition dynamics. We also include firm fixed effects and time\*type of firm (i.e. year \* Factoring dummy) to control for events that could have affected each company, and the industry in a different way over time.

Table 6 reports the main results. Specifically, we find the factoring dummy has a positive and significant coefficient with respect to firm stability. This means that factoring companies are (on average) more stable than banks. Second, we observe a positive and statistically significant link between market power and firm stability (both for the Lerner index and firm market share). These results support the competition fragility-view as firm stability increases when firm market power increases (and so competition declines) as well. Interestingly, we find that the interaction between the factoring dummy and our measures of market power is negatively and statistically significant. This suggests that the competition-fragility view is weaker in the factoring industry than in the banking sector. Finally, our findings show a negative link between size and firm stability. This suggests that firm stability declines (on average) as firm asset size increases.

As a robustness check, we also measure firm stability focusing on the CAR (columns 2 and 3). Results are strongly consistent, except for the link between the CAR and the interaction between market share and factoring. Specifically, *Market Share\*Factoring* impacts negatively on stability and positively on capital at risk; this would suggest that a consolidation process of the factoring firms with a consequent increase of the market share may increase their risk.

**Fig. 1. The evolution of competition indicators in the factoring industry.** This figure reports the evolution of competition and stability indicators in the factoring industry over time. Specifically, we report the Herfindahl-Hirschman Index for factoring companies (panel A: top left), measured with the outstanding value of trade credits at the end of the year (HHI-ANT) and the overall value of all trade credits in the year (HHI-TR). In the panel B (top-right), we report the Lerner index for factoring companies. In the Panel C (down-left) and D (Down-right), we report the HHI (calculated based on total assets) and the Lerner indices for banks, respectively. In all graphs, years: 1, ...,8 correspond to years: 2008–2015.

**Table 5**

**Comparing competition levels in factoring and leasing industry.** This table shows a two-sample *t*-test with equal variances for the Lerner index by comparing banks (group 1) and factoring firms (group 2) in the Italian credit industry between 2008 and 2015. The null hypothesis states that there is no difference between the two group means. The symbols \* and \*\* indicate significance at 5% and 1% levels, respectively.

| Group                    | No. Observations | Mean     | Std. Err. | Std. Dev. | [95% Conf. Interval] |       |

| (1)<br>Banks             | 515              | 0.488    | 0.009     | 0.214     | 0.469                | 0.507 |
| (2)<br>Factoring<br>Mean | 192              | 0.410    | 0.017     | 0.244     | 0.376                | 0.445 |
| (1–2)<br>Difference      | 707              | 0.467    | 0.008     | 0.225     | 0.450                | 0.484 |
|                          |                  | 0.077*** | 0.019     |           | 0.047                | 0.121 |

Note: \*\*\* $p < 0.01$ .

## 7.2. Impulse responses

In this section, we calculate the orthogonalised impulse responses of the banks' risk (competition) to competition (risk) shocks. Fig. 2 shows the results for factoring firms, while Fig. 3 shows the same for commercial banks. Fig. 2a shows the change ( $\Delta$ ) in the Z-score because of a shock to the Lerner Index. Instead Fig. 2b presents the results relative to change  $\Delta$  in the CAR as

Table 6

**Results.** This table reports the results of the regression where the dependent variable refers to firms' stability measures, respectively the log of the Z-score and the log of the Capital At Risk (CAR). The independent variables are: i) a dummy variable capturing the type of credit-institution (i.e. 1 for factoring firms, 0 for commercial banks), the Lerner index, the firm market share. We also control for firms asset size calculated as the logarithm of total assets. We include bank fixed effects ( $A_i$ ) and year\*factoring fixed effects ( $B_{y,t}$ ). Robust standard errors in parentheses are clustered at the bank level. \* and \*\* indicate significance at the 5% and 1% levels, respectively. All variables are defined in Table 3.

a result of a shock to the Lerner Index. The solid lines show the response of these variables. Instead the grey area represents the 95% confidence interval. We consider three periods for the simulation horizon.

Furthermore, we notice a significant and negative response of the Z-score to one standard deviation shock in the Lerner Index (Fig. 2a). Specifically, one standard deviation shock to the Lerner Index will decrease the Z-score visibly in the first period. However, such an effect appears to tend towards zero in the medium term. We show a similar pattern for the CAR. However, the size of the response of the CAR to shocks to the Lerner Index appears to be more marginal than the Z-score. Fig. 2b shows that the impulse-responses of the Lerner Index to risk' shock in the case of factoring firms. We note a statistically significant and negative response of the Lerner Index to shocks in the Z-score in the short term. In contrast, we notice that there is a significant and positive effect of the Lerner Index as the consequence of a shock to the CAR in the short and medium term (Fig. 2b). Particularly, after a slight increasing pattern, the Lerner Index declines again as the effect of a shock in the CAR. Therefore, we can argue that overall the Lerner Index exhibits a positive and significant trend to a one standard deviation shock in the CAR. Finally, we highlight that the confidence interval for the impulse-response function in the case of the CAR is rather large. Specifically, the confidence interval is wider after the first period. Even though we have transformed the data, we still find the existence of a heterogeneity effect in the response function of risk to change in competition. This effect is clearer after a single period of shock.

Fig. 3 illustrates the impulse response functions to the impulse-responses of risk to a shock to the Lerner index for commercial banks. Fig. 3a reports the impulse-response functions for the Z-score and the CAR to shock to Lerner Index.

Differently from factoring firms, we do not find any significant response of the Z-score to one standard deviation change in the Lerner Index (Fig. 3a). Instead, the Lerner Index appears now to significantly increase for the effect to shock of the Z-score. However, such an impact is only significant in the short-term. Turning to the CAR-Lerner Index linkage, we did not find any significant effect for any impulse-responses functions (Fig. 3b).

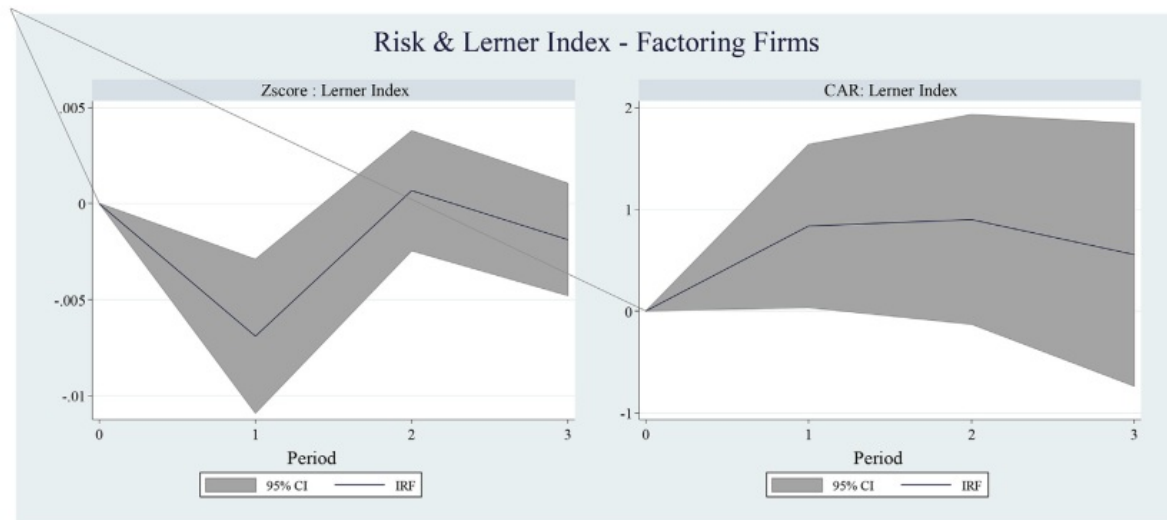

Table 7 shows the Variance Decomposition (VDCs) where the forecast horizons consists of three periods. Particularly, regarding the Lerner Index and risk relationship for the factoring industry, Table 7 shows that almost 3% variation in the Z-score is explained by shocks in the Lerner Index, while 16% of variation in the Lerner Index is explained by shocks in the Z-score in the factoring industry. Similarly, about 15% variation in the CAR is explained by shocks in the Lerner Index, while 40–50% of the variation in the Lerner Index is explained by the CAR for factoring firms (in the 2nd and 3rd period). In contrast, variations in the Lerner Index are not so relevant for the change of the Z-score and the CAR of commercial banks and vice versa.

### Panel A –Impulse: Lerner Index

Note Figure (a) Test of overidentifying restriction: Hansen's J  $\chi^2(12) = 23.507$  ( $p = 0.101$ ); Figure (b) Hansen's J  $\chi^2(12) = 12.939$  ( $p = 0.114$ ). Impulse: Lerner Index. Impulse Response Functions (IRF). 95% Confidence Interval (CI) generated by Monte-Carlo with 1000 reps

### Panel B –Impulse: Z-score and CAR

Note Figure (c) Test of overidentifying restriction: Hansen's J  $\chi^2(12) = 23.507$  ( $p = 0.101$ ); Figure (d) Hansen's J  $\chi^2(12) = 12.939$  ( $p = 0.114$ ). Impulse: Z-Score and CAR. Impulse Response Functions (IRF). 95% Confidence Interval (CI) generated by Monte-Carlo with 1000 reps

106

**Fig. 2. Impulse response functions for factoring firms.** This figure illustrates the impulse response functions (IRFs) of each endogenous variable with respect to one standard deviation shock in other variables for the factoring industry. We employ 1000 Monte Carlo simulations to get bootstrapped confidence intervals for the impulse response functions. We also subtract from each variable in the model its cross-sectional mean before estimation to remove time fixed effects. All variables are defined in Table 3.

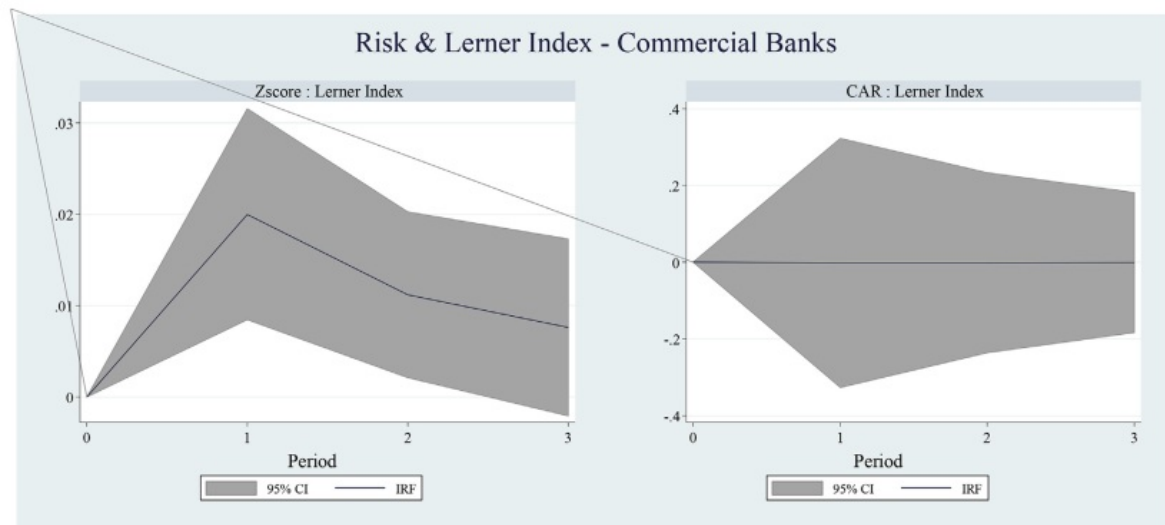

Panel A –Impulse: Lerner Index

Note: Figure (a) Hansen's J  $\chi^2(8) = 8.673$  ( $p = 0.371$ ); Figure (b) Hansen's J  $\chi^2(8) = 8.699$  ( $p = 0.728$ ). Impulse: Lerner Index. Impulse Response Functions (IRF). 95% Confidence Interval (CI) generated by Monte-Carlo with 1000 reps

Panel B –Impulse: Z-score and CAR

Note: Figure (c) Hansen's J  $\chi^2(8) = 8.673$  ( $p = 0.371$ ); Figure (d) Hansen's J  $\chi^2(8) = 8.699$  ( $p = 0.728$ ). Impulse: Z-score and CAR. Impulse Response Functions (IRF). 95% Confidence Interval (CI) generated by Monte-Carlo with 1000 reps.

101

2

**Fig. 3. Impulse response functions for commercial banks.** This figure illustrates the impulse response functions (IRFs) of each endogenous variable with respect to one standard deviation shock in other variables for the banking industry. We employ 1000 Monte Carlo simulations to get bootstrapped confidence intervals for the impulse response functions. We also subtract from each variable in the model its cross-sectional mean before estimation to remove time fixed effects. All variables are defined in Table 3.

Table 7

**Forecast-error variance decomposition.** This table reports the forecast-error variance decomposition (FEVD) based on a Cholesky decomposition of the residual covariance matrix of the underlying panel VAR model and again using 1000 Monte Carlo simulations. It shows the percentage of variation in one variable explained by the 'shock' (i.e. change) to another variable over three periods ahead. There are two models. In the first model, there are Z-score and Lerner Index, while in the second one there are CAR and Lerner Index. The models are presented for both the factoring and banking industry. All variables are defined in Table 3.

| Response variable and forecast horizon | Factoring Firms                | Commercial Banks | Response variable and forecast horizon | Factoring Firms           | Commercial Banks |
|--|--------------------------------|------------------|--|---------------------------|------------------|
|  | Impulse Variable: Lerner Index |                  |  | Impulse Variable: Z-score |                  |
| Z-score                                |                                |                  | Lerner Index                           |                           |                  |
| 0                                      | 0.000                          | 0.000            | 0                                      | 0.000                     | 0.000            |

## 8. Conclusions

Competition is seen to play a pivotal role in spurring greater efficiency, innovation, and generally in favouring a more efficient allocation of financial resources. However, the recent financial crisis has raised some concerns among scholars and policy makers on its role in stimulating higher bank risk-taking (Degl'Innocenti et al., 2019).

This paper offers new insight on the importance of the relationship between risk and competition for both the factoring and banking industry in Italy. To this end, we make use of a panel data model with firm, time, and industry fixed effects to analyse the relationship between risk and competition. Then, we use a panel VAR to examine the impulse responses of risk variables, Z-score and CAR, to changes in the Lerner Index, and vice versa. Our dataset encompasses 707 observations over 2008–2015.

We obtain three main results. First, factoring companies are (on average) more stable than banks. Second, the stability of factoring companies increases when firm market power increases as well (and so competition declines); this supports the competition fragility view. Third, the competition-fragility view is weaker in the factoring industry than in the banking industry. Overall, our findings indicate that competition in the Italian credit industry was greater in factoring than in banking.

Finally, we run a panel-VAR model to estimate banks' risk measures reaction to competition shocks and vice-versa. We find that factoring firms' response in the Z-score is significantly and negatively related to variation in the Lerner Index only in the short-term impulse responses in the factoring industry. Instead, we show that the Lerner Index decreases as the effect of a shock in the Z-score, while increases because of a shock in the CAR. This suggest that competition will increase as the consequence of one standard deviation change in the Z-score or decrease as the consequence of one standard deviation change in the CAR. Finally, we find empirical evidence that competition decreases (the Lerner Index increases) as the effect of one standard deviation shock in the Z-score in the banking industry. In other words, this finding suggests that as a bank increases its stability, it also consolidates its monopoly market power. As a counter effect, this can harm competition in the banking system.

Our paper provides important insights to policy makers, practitioners, and academics with regards to there being differences between factoring firms and banks in terms of stability (greater in factoring), competition (greater in factoring), and in their relationship (where the competition-fragility view is weaker in factoring). Overall, the factoring industry appears to be more stable than commercial banks and less vulnerable to financial crises because of the peculiarity of its business model. However, policy makers should be aware of the fact that the level of stability of the sector could decrease as the effect of the consolidation process and a consequent increase of the factoring firms' market share. Furthermore, the creation of a niche of specialization in terms of industrial and geographic markets (as in the case of the Italian factoring industry) could enhance both the competition and the stability of the financial sector.

## Acknowledgement

We would like to thank Pierpaolo Ferrari, and Stefano Monferrà for their collaboration. We also thankful to SDA Bocconi in Milan for providing us company-level data from the "Osservatorio sugli Intermediari Finanziari Non Bancari" (OSSFIN) and the Italian Factoring Association (Assifact) for providing us with industry-level data on the Italian factoring sector.

**Table A**

**Lerner index and risk: full sample.** This table reports the results of the regression where the dependent variable refers to firms' stability measures, respectively the log of the Z-score and the log of the Capital At Risk (CAR). The independent variables are: i) a dummy variable capturing the type of credit-institution (i.e. 1 for factoring firms, 0 for commercial banks), the Lerner index, the firm market share. We also control for firms asset size calculated as the logarithm of total assets. We include bank fixed effects ( $A_i$ ) and year\*factoring fixed effects ( $B_{yT}$ ). Robust standard errors in parentheses are clustered at the bank level. \* and \*\* indicate significance at the 5% and 1% levels, respectively. All variables are defined in Table 3.
